Friction: Slows the wind down. Surface air pressures can vary horizontally between two locations on the Earth's surface. This results in a difference in the number of ...

This exercise explains the forces that govern wind velocity (speed and direction) and provides a better understanding of weather maps. Knowing what makes the wind blow and change directions is ...

The stronger the speed (such as wind speed), the stronger the Coriolis force. The higher the latitude, the stronger the Coriolis force. The Coriolis force is zero at the equator. Coriolis force is one major factor ...

Wind results from a horizontal difference in air pressure and since the sun heats different parts of the Earth differently, causing pressure differences, the Sun is the driving force for most winds.

This lecture includes an overview of the wind and its various movements. Included in this discussion is an explanation of the pressure gradient force and the ...

The Coriolis force is caused by the rotation of the earth and always points perpendicular to the wind (to the right as you look downstream in the northern hemisphere and to the left in the southern ...

To show wind speeds, the pressure gradient is plotted onto ...

It's simple, really. Wind blows because of differences in air pressure or pressure gradient. The bigger the gradient, the stronger the wind. Wind blows from high pressure to low pressure on the ...

Big changes within shorter distances equals high wind speeds, while environments that exhibit less change in pressure with distance generate lower ...
